This paper has been prepared for presentation April 21,  
1980 at the Workshop in Political Theory and Policy Analysis,  
Indiana University, 814 E. Third St., Bloomington, Ind. 47401.

DRAFT: NOT FOR QUOTATION

THE INSTITUTIONAL FRAMEWORK FOR SAHELIEAN REFORESTATION:  
MICROCATCHMENTS, EXPERIMENTS AND LOCAL AUTONOMY\*

James T. Thomson

Introduction

This essay treats issues (Sahelian and expatriate foresters, Sahelian governments and foreign aid donor organizations now concede to be crucial to implementation of successful environmental management programs in the Sahel, that much-abused band of territory along the Sahara's southern fringe. Among these issues are: (1) development of effective techniques of reforestation and woodstock management; (2) involvement (and active participation) of Sahelian peasants in reforestation and woodstock management; (3) identification of appropriate institutional frameworks within which such actions can occur.

The author considers points (2) and (3) of primary importance. Their realization conditions possibilities of achieving point (1), reforestation and woodstock management, but goes well beyond environmental problems to lay the groundwork for provision of a broad range of public goods (soil conservation, and watershed management, (including) replenishment of groundwater tables; road maintenance; health and sanitation; education, etc.)

\*Materials for this essay were collected in Niger and Upper Volta (January 1979 - March 1980) during fieldwork authorized by the two governments and funded in part by the Rockefeller Foundation, Lafayette College, USAID and OXFAM. Appreciation for both authorization and funding is here expressed.

(not now readily available in many Sahelian communities.) By contrast, practitioners - foresters, governments and donors - often assume by and large that techniques of reforestation are the critical issue. (Institutional design considerations interest them only, if at all, as a means to reforestation.)

(In deference to the practitioners' perspective, the analysis below begins with the question of reforestation technique, (after some very brief comments about the assumptions upon which the analysis rests.) It focuses on the device of microcatchments as a technique of arid land reforestation, emphasizing the extent to which success of the technique hinges upon continued experimentation in adapting it to particular and highly varied Sahelian microenvironments. In a third section, the need for experimentation is taken as <sup>one</sup> a constraint, and paired with a second, the variability of local-level political environments in the Sahel. These constraints define <sup>parameters</sup> the characteristics of (the) institutional arrangements within which participatory reforestation and woodstock management would be feasible in the Sahel, <sup>These are</sup> set out in a fourth section. Implications of these arrangements are <sup>explored</sup> (considered) in a concluding section.

## Assumptions

The people whose behavior is here analyzed and who must implement any eventual solutions to reforestation problems in the Sahel are assumed to be self-interested, rational maximizers who make decisions under conditions of uncertain information (and therefore often satisfice rather than maximize). They do so within a basic legal framework which varies from place to place but establishes in any local context parameters of their decision-making processes. People are (also) assumed to be capable of learning over time as new information becomes available to them [V. Ostrom, 1974: 50-52].

## Reforestation: Technical Problems and Solutions

### Contemporary Sahelian Reforestation Efforts

Since the <sup>(1968-74)</sup> Sahelian drought, <sup>(1968-74)</sup> interest in <sup>(Sahelian)</sup> environmental management in the Sahel zone has increased enormously. <sup>(we have inspired much reflection and some creative efforts)</sup>

[Copans, 1975; Dalby, Church and Bezzaz, 1977; Glantz, 1977]. <sup>(Franko and (Hasin, 1980))</sup>

Reforestation projects have been launched as <sup>(one element of a broader)</sup> part of this <sup>(evolving strategy to promote better resource management)</sup> undertaking in many Sahelian areas. They vary widely in type,

from industrial greenbelt and firewood plantations sited around cities, to village woodlots, dune stabilization efforts and natural regeneration programs.

With the exception of industrial plantations, <sup>(where popular participation has no relevance)</sup> conceived and implemented without popular participation, <sup>(conceived)</sup> these projects

all (share) a common weakness: they fail in greater or lesser degree to involve rural people in project design and execution [Hoskins, 1979; Thomson, 1980a]. In some parts of the Sahel, <sup>reliance on</sup> family woodlots <sup>has produced a certain degree of</sup> (family-controlled reforestation efforts) have fared better because they avoid costs of <sup>inherent in government projects</sup> collective action, <sup>while state</sup> <sup>affiliated and</sup>

A second weakness, less <sup>commonly</sup> widely shared among these projects, nonetheless accounts for <sup>a</sup> considerable amount of <sup>the</sup> peasant disillusionment with woodstock management possibilities <sup>of</sup> planting techniques and species "packages" advocated by foresters and sponsoring agencies have frequently been ill-adapted to the task at hand. Survival rates after a single year, to say nothing of several, are <sup>disastrous</sup> (miserable) and tree growth <sup>is</sup> stunted (to the extent) that firewood production, for instance, is negligible [Thomson, 1980a].

These two weaknesses (appear interrelated and) mutually reinforcing <sup>each other</sup> They <sup>flow from</sup> reflect the top-down, authoritarian <sup>work</sup> style attitudes inherited from <sup>the</sup> colonial era Sahelian forestry services and perpetuated by most of today's foresters [Thomson, 1977]. <sup>Since local people usually do not feel invited to participate in an influential way, forest</sup> Individual peasants (have apparently) felt <sup>very</sup> little <sup>project planning</sup> commitment to <sup>state-run</sup> (externally-controlled) reforestation projects <sup>and therefore</sup> (and therefore) have made <sup>almost no</sup> (very little) attempt to involve themselves with program implementation or to experiment with variations on new techniques of reforestation. <sup>Yet</sup> (such) local <sup>commitment to</sup> (involvement in the) search for better methods <sup>affords the only realistic route</sup> (is probably indispensable) to effective <sup>Sahelian</sup> environmental management, given <sup>the</sup> (the) budgetary and staffing constraints under which most (Sahelian) <sup>area</sup>

forestry agencies (operate.) labor.

Problem: Finding Workable Reforestation Techniques

Foresters <sup>generally</sup> <sup>concentrate</sup> have focused on the second weakness mentioned above. Some donor organizations have <sup>shared</sup> (likewise) invested funds in <sup>identifying</sup> (improved) techniques or <sup>identifying</sup> species which might facilitate Sahelian reforestation [Thomson, 1980a; Thomson, 1980b]. Foresters and organizations evidently assume peasants will voluntarily participate in reforestation once a viable technical package of planting methods and appropriate species is worked out. Of course many foresters <sup>recognize</sup> are aware of other constraints <sup>impeding</sup> reforestation. (The surplus or deficit resource situation <sup>many know</sup> <sup>wood shortages</sup> in an area [Thomson, 1980c], land and tree tenure regulations, tenure enforcement problems, local collective action capabilities, protection possibilities concerning browsing livestock and wood-collecting humans, etc., (appear to) sharply influence villagers' willingness to <sup>manage</sup> become involved in <sup>their</sup> woodstock (management efforts) [Thomson, 1980d].

Nevertheless, foresters' training leads many (of them) to <sup>concentrate</sup> on technical issues. [cite book reference: Sylvic Africa 1980 White book: 200, p. 57, ...] ]

Microcatchments:  
A Solution?

Microcatchments for reforestation, a variation on ancient run-off agriculture techniques [Evenari et. al., n.d. (1976?)], (appear to) offer (some) promise as a wood-producing technique for the Sahel zone. Microcatchments (are deliberately constructed to)

create tiny hospitable environments for tree-raising (and food crop production, and possibly viniculture) in (the middle of) hostile, arid milieux characterized by relatively impermeable soils. Unless caught in the <sup>small, diked squares (or V's</sup> formed by little wing dams) and pit basins with their <sup>artificially heightened</sup> absorptive capacity, <sup>rain water (moves)</sup> immediately <sup>from</sup> such fields, often <sup>eroding</sup> precious topsoil as it does so, and disappears as surface run-off. <sup>(Without)</sup> <sup>sufficient water, intense heat, and extreme aridity</sup> sear ground cover. <sup>(Particularly where, as, in the)</sup> contemporary Sahel, <sup>population pressure, overcultivation and overgrazing</sup> compound effects of these harsh natural elements, <sup>environmental</sup> degradation <sup>is a sure consequence</sup> unless counterbalancing water management techniques are brought to bear on the problem.

The trick in microcatchment technology consists simply in corraling rain before it gets away. <sup>INSIGHT</sup> One then "stacks" enough <sup>inadequate</sup> rainfall from a larger area by draining <sup>off the catchment surface</sup> it into the pit basin. There the moisture accumulation makes plant life possible. <sup>The technique will work with average annual rainfall</sup> of as little as 100 mm. <sup>[Reference: ... (1976?)];</sup> <sup>Most of the Sahel receives annual rainfall of 200-600 mm. Annual ...</sup>

Three technical constraints condition <sup>(applicability)</sup> of the technique in any <sup>particular</sup> environment.

1. Soils must be highly impermeable, e.g., baked clay or laterite, to promote run-off drainage.

2. Similar soils or rocks must be available to construct dikes around <sup>(the)</sup> catchment areas. Material for dikes can

usually be had from the drainage trenches dug just inside the catchment perimeter to guide water into the basin.

3. It must be possible to dig a pit basin in the downhill angle of the catchment and fill it nearly full with improved, highly porous soils (mixing cinders, manure and vegetable matter with site soils <sup>is</sup> usually sufficient <sup>to do the trick</sup>). Since they are spongy rather than impermeable, pit soils suck up and hold run-off moisture.

While the technique won't work everywhere, e.g., in sandy soils, many local <sup>environments</sup> (across the Sahel <sup>are</sup>) <sup>technically</sup> appropriate <sup>for reforestation by this method</sup>. Microcatchments can be used <sup>(by individuals or groups in isolation on cultivated fields or played-out hardpans)</sup>. They can be associated with slightly more sophisticated contour diking or terracing schemes designed to stem soil erosion and heighten agricultural productivity. Where mechanical earthmoving equipment is available to shape dikes or terraces, microcatchments can be integrated into an overall watershed management/soil conservation scheme initially as part of planned development, or as an afterthought embellishment to enhance benefits of water control.

Even without machines, local hand tools almost always suffice, given perserverance and a bit of astuteness <sup>)-</sup> which any peasant can manage <sup>-</sup> in timing construction for the post-harvest period. Clay soils are then normally still friable, having not yet hardened under the baking sun. Laterite pans pose a more

*condition  
conspicuous  
in  
washing activities*

difficult problem, but many have not yet solidified. The process of formation can be reversed or appropriately manipulated to maintain in productive uses large amounts of land which would otherwise be irreparably lost.

Microcatchment Major Variables  
and Field Experiments in Yatenga

In 1978 OXFAM, a private voluntary organization engaged in development assistance, initiated a multi-faceted microcatchment experiment in eight villages of the Sahelien Yatenga region of northern Upper Volta [Thomson, 1980b]. It was hoped a workable reforestation "package" might be perfected and then spread through extension work elsewhere in Yatenga and comparable Sahelien regions.

The experiment involves manipulation of five different technical variables under the kind of field conditions typical of Yatenga rural life:

1. soil and site types;
2. appropriate varieties (and combinations) of trees, bushes, food crops and vines;
3. catchment shapes and dimensions;
4. planting dates; and
5. fencing trials.

Efforts were made, on markedly different soils (soil quality, extent of soil degradation) and site types (slopes, drainage characteristics), to test local and exotic species in <sup>square</sup> catchments ranging in size from ~~ten by ten~~ <sup>and to measuring eight to ten meters on a side</sup> ~~(to six by six)~~ meters. Varying catchment size and dimensions <sup>will modify</sup> water harvesting

capacity. Thus (the amount of) water collected can be varied to fit the requirements of different species. Furthermore, the simpler the construction job (smaller catchments or open V's rather than closed squares), the less effort <sup>is</sup> required to complete it; and the greater the attractiveness of the investment. Planting dates were also manipulated; results to date, six to nine months after planting, generally suggest most species fare better when planted earlier. The Sahelian dry season is so brutal vegetation not well established when it starts has little chance of surviving the parching heat which precedes the next rainy season seven to nine months later. Finally, fencing trials sought to assess feasibility of traditional methods of protecting trees from browsing livestock and extent to which project success might depend on manufactured inputs (barbed <sup>wire</sup> or <sup>parking</sup> hog wire, fence poles).

One significant conclusion can already be drawn from the first year's experimentation: there is very little likelihood that a reforestation "package" can ever be perfected for mindless replication across the entire range of Sahelian micro-environments. These are too varied, both in physical terms and in the kinds of uses human and animal communities make of them. On the other hand, variations on the technique might well facilitate woodstock management in quite diverse areas already seriously deforested.

The critical importance of local flexibility in Sahelian reforestation activities flows from three causes:

1. variable climate (especially spacing and amount of annual rainfall);
2. variability of soils and terrain generally; and
3. variability of the human communities superimposed on those soils. Different to begin with, they change and evolve, as do sizes of the herds they hold and their arrangements for keeping them.

Common characteristics do, of course, occur across most or all milieux of the Sahelien zone: generalized aridity, unpredictable rainfall, low standards of living, etc. But the margin of accuracy or error, success or failure of any single reforestation strategy lies unquestionably in the extent to which it can effectively accommodate local differences scattered across the backgrop of these commonalities.

Local Sahelien environments vary greatly. Many are experiencing rapid evolution - not a lot of it good in the sense of improving chances that local places can go on supporting current populations indefinitely. This variability imposes a major and powerful constraint, often underestimated, on any plan to centrally manage the Sahelien environment, either on a state-by-state basis or on some sub-state, regional basis.

#### Varied Political Environments

Assuming experimental adaptation to local environments must be an integral part of any future attempts to employ microcatchment technology in Sahelien reforestation ventures, is it possible to do so without popular participation?

Sahelian forestry services, by all accounts, are not terribly efficient producers of public goods. Analysts suggest a number of reasons.

1. These services operate within physically difficult terrain once they leave urban headquarters and move into rural areas where most Saheliens live. Communications are poor. With relatively few exceptions, roads are unpaved and frequently nothing more than dirt tracks, sometimes impassable during the summer rainy season when many important forestry activities occur. Telecommunications are also extremely limited. Contact with rural populations is thus expensive and intermittent.

2. Sahelian bureaucracies often lack funds for supplies. This is particularly true of Sahelian forestry services, which have traditionally taken a back seat to other more directly productive rural development agencies (e.g., agriculture services) in terms of budgetary allocations.

3. By the same token forestry services are frequently understaffed and <sup>their personnel</sup> inappropriately trained. <sup>Foresters focused on R & D, etc.</sup> (Foresters focused until very recently) almost exclusively on industrial plantation techniques and forestry code enforcement procedures. They lack the sort of background in rural, local-level experimental forestry which would make them effective extension workers.

4. Sahelian forestry services, like Sahelian government bureaucracies generally, do not provide employees with strong incentives to make the kind of consistent efforts necessary to produce public goods, e.g., reforestation or environmental

management [Thomson, 1977]. Sahelian foresters frequently find occasions to extract benefits from their official positions without being compelled in any way to render equivalent services to the public whose tax monies largely support them.

5. The above <sup>almost totally erode value</sup> factors <sup>(combine)</sup> to vitiate the typical sort <sup>e</sup> of centrally-initiated reforestation activities now characteristic of the area. Even when <sup>(top level foresters obtain) technical</sup> adequate information is available to supervisors at the top of forestry service bureaucracies, it is extremely difficult <sup>(they can)</sup> to communicate <sup>(it)</sup> that information to the local level and <sup>(see)</sup> have <sup>(only with great difficulty)</sup> it effectively utilized there. Thus the typical top-down approach to Sahelian woodstock management <sup>(has)</sup> come in <sup>(faces)</sup> for increasing criticism, not only among donor agencies and governments interested in environmental management problems, but among Sahelian chief foresters who <sup>(bear)</sup> have primary responsibility for solving those problems. They find they cannot induce their subordinates to effectively manage the woodstocks under their control.

#### Local Participation in Reforestation

(Is it possible to convert <sup>(can)</sup> peasants <sup>(be converted)</sup> from by-standers passively observing degradation of their environment to "barefoot scientists" actively engaged in a search for better techniques of woodstock management? <sup>(Answering)</sup> The answer to this question involves <sup>(grappling with)</sup> the problem of local political organization.

Sahelian local communities, and not infrequently levels

below (quarters, families and voluntary associations) and above (inter-village ad hoc associations for specific purposes, government-created institutions for inter-village cooperation)

vary dramatically in their collective action capabilities. Yet Sahelian

*(and local forestry) force reforestation activities into*  
attempts to impose a single organizational format for

reforestation activities from the center are quite common.)

All risk aborting (the) programs they *(wish)* (are trying) to promote by assuming <sup>all</sup> villages *(conform to)* (fit) standard organizational patterns.

Thus attempts to induce Sahelian peasants to seriously commit themselves to microcatchment experimentation *(are flatly incompatible)* while at the same time *(with programs)* dictating (the) formats within which *(the search for workable techniques)* such experimentation must proceed *(with programs)* will almost certainly produce sub-optimal results in terms of woodstock management. *(if the chance to produce results at all)* Some communities *(may)* will probably respond readily to an imposed organizational format because it *(largely by accident)* (accidentally, in most cases) corresponds to (to) realities of local political structure. It may correspond to the only organizational possibility, e.g., a village collective woodlot project will likely prove successful in a village accustomed to functioning as a common unit for all public good purposes. *(It may)* on the other hand, correspond to one of the local repertory of organizational possibilities. *(That is, e.g.,)* the same project might well *(Succeed)* (be successful in a community) where villagers *(often)* (are accustomed to working) in large scale local collective enterprises as well as in smaller (quarter or voluntary) groups and individually.

By contrast, the same project would predictably fail in

<sup>Letting members</sup> communities which lack the capability of getting together to realize common objectives.

The OXFAM experimental microcatchment project nicely illustrates the point [Thomson, 1980b: 20-21]. (The project was initiated on the assumption that a collective format <sup>was thought</sup> would be) adviseable. However the project director did not blindly assume all Yatenga villages would <sup>offer</sup> (be) equally appropriate locations for the experiment. Instead, she requested advice from extension work <sup>ers</sup> organizers resident in the Yatenga regional capital, Ouahigouya. They directed her to six villages (which had reputations as being <sup>believed to be</sup>) highly motivated and collectively organized. Each of these communities agreed to participate. Subsequently two quarters of a seventh village requested <sup>to be</sup> included as separate units in the program. This was done, making a total of six villages in which some members of <sup>most or</sup> all (or most) quarters participated collectively, and two quarters of the seventh village participating as distinctive units.

The experiment then proceeded. <sup>Village groups built</sup> Various kinds of micro-catchments were created through voluntary self-help at the eight sites (proposed by participating villagers.) OXFAM's <sup>limited its</sup> contribution (was limited) to technical advice and minimal material inputs (hand tools and, in several communities, barbed wire or metal packing bands as fencing components). (Villagers did all the work of <sup>Peasants had to</sup>) constructing the catchments, planting, trees, and maintaining) and fencing.) They provided fence poles and, in some cases, traditional woven or teepee enclosures for trees.

*performance levels varied severely*

Representatives of five of the eight groups involved were interviewed approximately eleven months after the projects were initiated to gather information about their perceptions of the experiments. Of these groups, four were ethnic Mossi and one was Foulse. Striking variations appeared in their opinions about the most appropriate organizational format for the project.

Four approved (the) collective organization of the supervised trial period in which trees were planted on a common plot.

1. One of these villages, a Mossi community, intends to continue the project autonomously both on a collective plot and by collective labor on individual fields over a period of years. This group will plant some members' fields a first year, some a second, still others a third.

2. A second village, Fulse, expects to continue the project autonomously, if the technique proves successful, only on individual fields. (Parents intend to) They will do so by collective labor exchanges, but these will all occur within single years. All group members (and must be having equal) must have the same amount of work done on their fields each year. Asking some to wait (another) year for their turn is perceived as placing too great a strain on collective action capabilities.

3., 4. The third and fourth villages, Mossi, expect to continue the project autonomously, if successful, only on individual fields and only with family labor.

5. The fifth village, Mossi, refuses to continue with the

supervised collective trial phase on a common plot unless paid to do so. However, if the technique proves successful, individuals <sup>will</sup> expect to <sup>introduce</sup> it gradually on their own fields using family labor <sup>exclusively</sup>.

(All of these five villages <sup>are</sup> located) within thirty kilometers of <sup>each</sup> other, in comparable Sahelian environments. All are situated within one traditional Mossi kingdom, Yatenga. All currently lie within a single Voltaic subprefecture, that of Ouahigouya. All operate the same sort of mixed farming-herding economy. Labor migration is substantial in each community. Religious differences <sup>do</sup> exist, and differences as well in the extent of local participation in the Ouahigouya commercial center. <sup>But these</sup> (The latter) do not, however, correlate with pronounced individualistic orientations, <sup>concerning reforestation activities.</sup>

A second illustration is provided by a village woodlot program in Zinder Department, Niger, financed by the Canadian International Development Research Centre (IDRC) [Thomson, 1980a]. Implementation of the program was entrusted to the Nigerien Forestry Service. A collective format was imposed. Of approximately twenty villages investigated, residents of all but one <sup>reported a strong preference for</sup> would have preferred to see the project carried out within an individualistic framework. This reflects local political realities in the region, where village collective action capacity <sup>has been checked</sup> is extremely limited. The result of an <sup>inappropriate</sup> organizational format here <sup>provoked</sup> was large-scale popular

disaffection with the enterprise, a total lack of local initiative in experimenting with improved planting techniques or better species packages, and a dreary disregard of even the most minimal maintenance operations, e.g., repair of fallen fences universally judged to be indispensable to protect the planted saplings <sup>at least at the moment</sup> from browsing livestock. <sup>(see p. 15)</sup>

### Appropriate Institutional Formats for Sahelian Reforestation Projects

These examples (and many others [Hoskins, 1979]) strongly suggest successful reforestation and woodstock management projects in the Sahel <sup>(incorporate)</sup> will build into project designs from the initial phases a very strong local option component. <sup>Several factors dictate this</sup> (This is dictated by a number of factors.)

First, certain scales of organization are implicit in any project. One must ask whether <sup>can</sup> a given reforestation technique can be handled <sup>by</sup> (at the level of the nuclear family on an individual peasant's fields? (To answer this one must address issues of) labor <sup>required</sup> inputs (for site preparation, (and) planting, and (of) post-planting protection. <sup>shape the answer to this question</sup> If techniques employed <sup>permitted</sup> (mean) a single adult <sup>to</sup> (can) successfully plant trees) without outside assistance, family level operations <sup>seem</sup> (are) indicated on that score. But the local political culture may involve a preference for collective organization, <sup>exemplified by</sup> as in the first Mossi village cited above (p. 15).

If protection is not a problem, the family seems the

appropriate unit. If it is a problem, and economies of scale can be realized by fencing larger areas, then assuming land tenure rules make site acquisition possible, some supra-nuclear unit offers a lower-cost solution. But how "supra"? Will the extended family do? What about the quarter? A group of quarters? Or the entire village? And so on.

These questions all have quite specific local answers, shaped individually by rates of interaction and levels of consensus within and between various units. "Working rules" of these units govern what conduct can be group-controlled and where individuals' areas of freedom lie. (These) answers <sup>(Although it might be possible to find some answers, probably only, can only be found in working rules, by local political entrepreneurs, with local control of resources, and the operation of systems relative to needs)</sup> can only be found in working rules, by local political entrepreneurs. (This) appears likely if one assumes such organizations must be developed throughout the Sahel in practically all villages in order to assure effective reforestation operations. No outside organization, national or international, could finance the sort of detailed, on-the-ground explorations necessary to produce the required information which <sup>(local people)</sup> already possess. It is cheaper and more efficient to allow them <sup>(villagers)</sup> a range of options, and freedom to experiment with new forms and processes of reforestation if they so choose. Data from the five-village investigation cited above amply confirm this proposition.

Second, local collective action capabilities vary. (There may be prior experience with) autonomous, village-wide organizations <sup>(may exist in some instances)</sup> (If is important to know, in turn, <sup>But</sup> for what purposes <sup>some</sup>

Must be made by  
villagers  
themselves

such organizations <sup>(can they be adapted for reforestation programs?)</sup> (have) functioned? Is <sup>(the)</sup> village leadership elite <sup>(can a community scale be)</sup> clearly identified, or will organizing things <sup>(at that</sup> scale) unleash protracted in-fighting as political entrepreneurs struggle for control of reforestation operations? Can those struggles be expected to frustrate activity while they last? Perhaps the village then isn't the best unit.

Third, other levels of organization within the community may be (1) competent and (2) authorized to tackle reforestation projects. If so, it might be very useful to encourage participation through them.

Fourth, if reforestation is a new activity, leadership authority may not be easily transferable from one or more traditional activities to the new enterprise. This implies questions <sup>concerning</sup> about <sup>whether</sup> pre-existing expectations about how organizations will be run can be "imported" to the new arena of activity. If so, fine. If not, some people are going to have to learn to lead in the new arena. This involves establishing authority to do so. <sup>about authority systems and authorities</sup> Consensus building, typically takes time, and is often costly. Too costly? Only local people can know.

### Conclusions and Implications

Conclusions will by now be fairly obvious. Sahelian reforestation, industrial plantations excepted, depends on careful tailoring of projects to local physical and political

capabilities. This cannot be accomplished, on any reasonable estimate of the present organizational and information-gathering capacities of Sahelian forestry services, from the top down. Therefore much greater attention must be devoted to creating project structures (which will) permit local definition of institutional frameworks appropriate for particular milieux. Only then will the popular participation and popular experimentation necessary for project success be forthcoming.

### Implications

Currently, <sup>(extremely strained)</sup> relationships <sup>exist</sup> between foresters and peasants are strained in many parts of the Sahel. (This follows from) the essentially repressive orientation still pursued by most Sahelian foresters in execution of what they define as their principal duties. <sup>(make this mandatory)</sup> Very few engage in extension work, although this is now beginning to change.

It is imperative to modify foresters' approach if peasants are ever to engage in willing and cooperative research with Sahelian foresters for solutions to woodstock management problems. So long as peasants see foresters as policemen they will avoid interactions with them to the extent possible. When interaction is unavoidable, they will confine themselves to submissive obedience to foresters' instruction] so long as foresters remain on the spot to enforce them. Once they leave, those instructions will be honored in the breach only.

Such relationships are not conducive to the kinds of information flow implicit in extension work. Peasants who are afraid to <sup>fear</sup> discuss <sup>long</sup> forestry problems with foresters are not likely to improve their knowledge of reforestation possibilities. Even less are they likely to take the risks involved in any kind of experiment. In consequence, the Sahelian environment is likely to erode totally from overuse, abuse and neglect.

In effect, cooperative relationships between peasants and foresters will only arise when foresters become dependent upon peasants for career rewards. Otherwise, the old domination relationship with all its negative consequences will persist. Some Sahelian political leaders apparently <sup>(see)</sup> are becoming aware of <sup>the</sup> the necessity for change. President Seyni Kountché of Niger <sup>(now)</sup> <sup>(is)</sup> <sup>(advocating)</sup> a program of local autonomy which may do much to restructure official-peasant relations in favor of greater cooperation among the two groups. Monumental problems nonetheless remain to be overcome before this policy can be implemented in Niger: presidential speeches will not alone change bureaucrats' perceptions of their own self-interest. Other Sahelian states face similar dilemmas, made perhaps more intractable by smaller budgets and a less bountiful endowment of natural resources.
