**International Research Workshop on 'Gender and Collective Action'
October 17-21, 2005 • Chiang Mai, Thailand**

The [CGIAR Systemwide Program on Collective Action and Property Rights](#) (CAPRI) is an initiative of the 15 centers that belong to the Consultative Group on International Agricultural Research. The initiative promotes comparative research on the role played by property rights and collective action institutions in shaping the efficiency, sustainability, and equity of natural resource systems. CAPRI's Secretariat is hosted by the [International Food Policy Research Institute](#)'s (IFPRI) Environment and Production Technology Division (www.ifpri.org).

CAPRI Working Papers contain preliminary material and research results and are circulated prior to a full peer review in order to stimulate discussion and critical comment. It is expected that most Working Papers will eventually be published in some other form, and that their content may also be revised.

ACKNOWLEDGMENTS

Brent Swallow and Elizabeth Were acknowledge financial support from the European Union and USAID, contributions of Ben Crow and Ruth Meinzen-Dick who helped to shape these studies, the Roy family who approved the publication of Jessica's work, and our many colleagues who assisted with the field studies, particularly Daniel Bundotich, Leah Onyango, Kenneth Bii and Rosemary Chemeli. We also acknowledge the members of the Chesilot group who generously provided information about their inspired efforts at water management, especially Reuben Tanui and Joseph Keter. Juan Camilo-Cardenas and Ben Crow provided very useful comments on a previous draft of this paper, most of which have been incorporated into this version of the paper.

This paper is dedicated to the memory of our close friend and colleague, Jessica L. Roy.

ABSTRACT

Safe water is widely recognized as both a fundamental human need and a key input into economic activity. Across the developing world, the typical approach to addressing these needs is to segregate supplies of water for domestic use from water for large-scale agricultural production. In that arrangement, the goal of domestic water supply is to provide small amounts of clean safe water for direct consumption, cleaning, bathing and sanitation, while the goal of agricultural water supply is to provide large amounts of lower quality water for irrigated agriculture. A new third use of water is now being given more attention by researchers: small amounts of water employed in selected household enterprises. This third use may be particularly important for women. There is a potential, therefore, that provision of modest amounts of water to smallholder farmers can enhance household economic production, save labor time for women and girls, and improve family health.

This paper adds to the merger literature on the multiple values of improved water supplies – improved health, time savings, and small-scale production for individual farmers and collectives – for the case of a rural community in the western highlands of Kenya. With minimum external support, two groups in this community have managed to install and operate systems of spring protection and piped water to their members' homesteads. Members of those households, particularly women, have benefited substantially in terms of time savings, health and small-scale production. The experience of this community also illustrates some of the challenges that must be faced for a community to effectively self-organize the investment and maintenance of a community-based water scheme. There are challenges of finance, gender relations, and conflict over scarce water supplies, group leadership, enforcement of community by-laws, and policy. Data from a census of springs in the same area show that successful collective action for water management is unusual, but certainly not unique, in this region of Kenya. Although women emerge as the main beneficiaries of improved water management in the community, their substantial contributions are largely hidden behind social norms regarding gender roles and relations. Research methods need to carefully triangulate information sources in order to clarify the very substantial and active roles performed by women. Kenya's water policy should be modified to better recognize and facilitate small-scale community-based water projects.

Water, Women, and Local Social Organization in the Western Kenya Highlands

INTRODUCTION

A major effort is required in this decade to fulfill (the MDG) commitments and extend access to these essential services to those who remain unserved, the majority of whom are poor people. As women play a central role in water provision and management, a special emphasis will be placed on ensuring the participation and involvement of women in these development efforts. (Kofi Annan, <http://www.un.org/waterforlifedecade/>)

Analysts studying Asian irrigation systems began to recognize the multiple-use nature of water supplies several years ago (Meinzen-Dick and Bakker 1999). While domestic and multiple use of irrigation water may be seen as a problem by irrigation managers, it can also be seen as an important reality that must be considered by all those who design and manage irrigation systems. For example, it may be possible to organize irrigation channels and reservoirs to deliver safer supplies to household users before reaching fields that may have runoffs of phosphorus or pesticides.⁴ Accommodating multiple uses of water may be complicated by social relations that are systematically

⁴ Personal communication with Susan Poates, describing traditional canal irrigation systems in the Andes region of northern Ecuador, September 2005.

biased against groups such as women, landless people, pastoralists, small-scale industrialists, or downstream irrigators.

While irrigation dominates agriculture in much of South Asia, it is relatively unimportant in Africa. Across the vast parts of the landscape that depend mostly on rainfed agriculture, the potential for multiple use of water systems is through the use of rainwater harvesting and domestic water supplies for small-scale agricultural production (Rockstrom, Barron and Fox 2003). Moriarty et al. (2004b) present an excellent case study of the value of water in small-scale agriculture for the Buckbridge community in South Africa. Drawing upon these and other case studies, Moriarty et al. (2004a) propose that quantities of water as small as 50 – 200 liters per capita per day can make big impacts on small-scale agricultural production, home industry and people's overall livelihoods. Moriarty et al. (2004a) therefore proscribe changes in policies and programs affecting water supply, relating particularly to the South Africa policy of guaranteeing access to a minimum of 20 liters per capita per day. Across East Africa, however, little research has been done on the actual or potential value of water supplies that go "beyond domestic" needs.

Across the global South, men's and women's divergent social positions lead to differences in water use, water rights, and access to water (e.g., Meinzen-Dick and Bakker 1999; Zwarteveen and Meinzen-Dick 2001; Crow and Sultana 2002). In many societies, women have the primary responsibility for completing domestic work, including collecting water. Furthermore, in many societies, women's and girl's reproductive work and other unpaid labor are not considered 'real' work. Across the globe, particularly in non-industrialized countries, men control land, finances, industry

and government and thus men tend to control access to water (Crow and Sultana 2002). Legal or formal water rights (rights to control water) are typically vested in farmers or household heads, typically men. Water management structures – from the local to the basin level – tend to be dominated by men, particularly large-scale water users and administrative, political and economic elites (Guerquin et al. 2003).

The East African country of Kenya is characterized by limited freshwater resources and high rainfall variability. It receives less than 650 square meters of freshwater per person per year, making it one of the most water scarce countries in Africa and the world (WRI Earthtrends 2003). Water scarcity is further compounded by extensive degradation of existing water resources, increasing vulnerability of rainfall, and periodic droughts and floods. Much of the rain falls in less than 20 percent of the country; the rest of the country is arid and semi-arid.

Kenya's water resources have been mismanaged through unsustainable water and land use policies, growing pollution and increasing degradation of rivers, lakes, wetlands and catchments. The water sector is known for low levels of investment, with most infrastructure now old and dilapidated. National-level data show that about 12 percent of rural Kenyans have household water connections (WHO / UNICEF 2004) and approximately two-thirds of poor rural households depend on unprotected sources of water (wells rivers, lakes, ponds and rainwater) in all seasons (Katui-Katua 2002). Virtually no progress in reducing the proportion of people reliant on unprotected water sources has been made over the last 10 years (WHO / UNICEF 2004).

In Kenya, women and children are generally responsible for domestic water-collection and management (Huggins 2000). Women make choices about the water they

collect. Many women must decide between a water source that is distant providing higher quality water and one that is near but providing lower quality water (Nyong and Kanroglou 2001; Crow and Sultana 2002). The amount of time women spend collecting water affects the amount of time they have for education and paid work. In Kenya, as in many societies, women's and children's reproductive work and other domestic labor are not considered "real" work (Suda 1996). Suda posits that social and cultural norms have naturalized women's domestic roles. Cultural norms in much of the world most likely serve to undervalue domestic work. However, Whittington et al (1990) estimated the value of time spent collecting water for households in Ukunda, Kenya and found that time spent collecting water was nearly equal in value to the wage rate for unskilled labor.

One option for expanding the coverage of safe and productive water supplies is to empower individual households and community groups to undertake and operate appropriate water supply infrastructure. With most of its population living on the slopes of the country's five "water towers" (the Aberdares Range, Mount Kenya, the Mau Forest Complex, Cherangani Hills and Mount Elgon), there is great potential for communities to protect and harness water from natural springs. Research on gender, social relations and water has been initiated in the Nyando river basin, where it was known that springs are a major source of household water supplies. This paper reports results from the village of Kiptegan, a village in the Western Kenyan highlands. Kiptegan is a relative success story, a village where community groups are mobilizing for improving water supplies. The Kiptegan case was uncovered in the course of research on poverty and property rights dynamics recently undertaken across the Nyando basin (Swallow et al. 2005). Results presented in this paper focus on gender relations, social organization, gender-

disaggregated impacts, and the challenges of uncovering the multiple contributions of women to local water management. The two objectives are to (i) identify institutions, processes and challenges that affect successful water supply to rural communities; and (ii) identify and quantify the role of water-based activities in improving livelihoods of the rural poor, in addition to hygiene and health benefits.

BACKGROUND

Kenya's National Water Plan of 1974 committed the Government of Kenya to ensure availability of potable water, at reasonable distance, to all households by the year 2000 (Water Master Plan 1974). In the 1980s the government began to experience more severe budget constraints and it became clear that, on its own, it could not fulfill this commitment. Attention therefore turned to finding ways of involving others in the provision of water services in place of the government, a process that came to be popularly known as "handing over."

In 1983, the government policy of district focus for rural development became operational, shifting increased responsibility to districts in order to encourage local initiative and improve local capacities. This, together with *harambee*, the local spirit of working together which was introduced at independence in 1963, gives the general framework for community management of water supply systems in Kenya (Oenga and Ikumi 1997).

The Water Act of 2002 prescribes very different roles for the government. The revamped Ministry of Water and Irrigation has become mostly a policy-making and coordinating agency. Responsibility for management of water resources is now vested in

the semi-autonomous Water Resources Management Authority, and responsibility for regulating water services is vested in the Water Service Regulatory Board. A new fund, the Water Services Trust Fund, has been established to channel external resources for water supply to disadvantaged communities.

In this new institutional setting, water provision is now seen as the role of private enterprises and non-governmental organizations. Under the Water Act of 2002 there is no clear recognition of the role of community-based organizations, despite evidence of their importance. Njonjo and Lane (2002) found that of eight million people who have access to improved water in the rural areas, 30 percent are served by community managed water supply schemes developed by self help groups. Njonjo (1997) found that community water associations are diverse in nature and capacity, ranging from fairly sophisticated systems with well structured tariffs to simple gravity schemes operated without any formal processes.

While Kenyan law requires self-help groups to be formally registered, there is no specific legislation governing how they work. For instance, non involvement of women as formal members in community water associations is a common denominator of water projects in the upper Nyando basin. Suda (2000) found women's participation in environmental conservation in Nyando and Kericho districts to be low. Part of the explanation was that women's farm work and household responsibilities divert their time from conservation activities. Also, activities performed by women were perceived as extensions of their domestic work and not as additional responsibilities.

Overview of study area

Kiptegan village is located in Ketutui sub-location, Ainamoi Division, Kericho District in the Western highlands of Kenya. The area is located in the upper catchment of the Nyando river basin, an area of about 3500 square kilometers that drains into Lake Victoria through the Winam Gulf. Rainfall in the Nyando basin varies from 700 to 2000 mm per year, and elevation varies between 1100 and 3000 meters above sea level. Population density in the basin ranges from less than 50 to over 1000 persons per square kilometer. The prevalence of absolute poverty ranges from over 70 percent poor to about 30 percent poor across the administrative locations in the basin. HIV / AIDS prevalence is very high, particularly in the areas occupied by Luo people on the flood plains near Lake Victoria. Patterns of land tenure, human settlement, and farming systems have been largely shaped by the pattern of colonial and post-colonial settlement that unfolded over the last century (Onyango, Swallow and Meinzen-Dick 2005).

Relative to much of the Nyando basin, Kiptegan village is relatively well resourced. It is located at about 2000 meters above sea level, receives average annual rainfall of about 1500 mm, and is located near the large market town of Kericho in a major tea-growing area. By Kenyan national standards, poverty is relatively low (30-40 percent), and community groups describe an even lower rate of poverty according to their own definitions (Swallow et al. 2005). The area is inhabited by people of the Kipsigis ethnic group, a Nilotic Kalenjin-speaking people. Major farming activities in the village are maize production for sale and consumption, livestock keeping, dairy farming and tea growing. Land tenure is freehold and adjudicated, indicating that the area was a native trust area during the colonial period. Improved water resource management is an important priority for communities throughout the basin (Swallow 2005).

Water supply and water resources in the study area

Government involvement in improving water supply in Kericho district is limited to provision of technical advice to user groups. The Water Department issues the abstraction permit after checking the quality and potential quantity of the discharge from the spring eye. As in many parts of Kenya, local authorities in Kericho are short of funds to invest in improving and expanding water systems, or even to maintain operating systems. The only government agency currently supplying water in Kericho district is the National Water Conservation and Pipeline Corporation, which operates a pumping scheme that covers 20 square kilometers.

A census of springs in five administrative divisions of Kericho district was undertaken in early 2005 in order to better understand the importance of springs as sources of drinking water and the prevalence of different types of spring management. Springs were classified into three groups: unprotected springs had no obvious physical improvement and little social organization around spring use; protected and not piped springs had some obvious physical improvement and a minimum of social organization to maintain that investment; and protected and piped springs had constructed tanks and pipes that carried the water by gravity flow to downhill water taps. The census uncovered 135 springs, 85 (63 percent) of which were unprotected, 24 (18 percent) of which were protected and not piped, and 26 of which were protected and piped (19 percent). Of the 24 protected and not piped springs, 11 were mostly self-organized by community groups, while 13 were mostly organized by external agencies. Of the 26 protected and piped springs, 13 were mostly self-organized by community groups, while 11 were mostly organized by external agencies (D. Bondotich, unpublished results from spring census of Kericho district 2005). The Water Act of 2002 implies less government

support and more regulation of small community groups, further threatening the viability of community-based water supplies.

Evolving gender ideologies in Kipsigis society

In pre-colonial and early colonial Kipsigis society, men had a right to inherit and hold predominant control of land and livestock. Men's rights to property were circumscribed by the fact that women were regarded as heads of 'houses,' with residual rights of control, and the right to pass land on to their male heirs. Women's status and power were further sustained by their position as producers, processors and traders of food crops (Ochardson 1961; Peristiany 1939). By having sole control over harvested grain, women were vital in their husbands' prestige and wealth and possessed considerable influence over the ways that power and influence were consolidated in the community.

Colonization and commoditization led to the privatization of land and the introduction of new crops for exchange. The introduction of maize as the staple food changed the existing division of labor; women continued to cultivate millet on a small scale but maize production and trade with maize came to be regarded as men's 'business'. Since maize was for both consumption and trade, women were obliged to work on their husband's field as helpers. Thus women changed from being autonomous millet producers to being unpaid family laborers. In addition, women's customary rights to the means of production were limited when land adjudication registered land in the names of men. Today, men thus own and control the major means of production and economically significant resources. They acquire exclusive rights to productive and reproductive services of their wives through payment of bride wealth. A man's

responsibility is to raise money to cover major household expenses by engaging in income-generating activities and through wage labor. Women's fundamental roles in the household are to provide food, care for the children, carry water, tend cattle, keep the house clean and do whatever the husband wants her to do, e.g. help him in the tea field (Sorensen 1990).

Research Methods

A study of poverty and property rights dynamics in the Nyando basin was conducted in 2004-5, including an intensive survey of 14 villages distributed across the basin. Villages were selected to be representative of 12 distinct zones in the basin, with zones defined by ethnicity (dominantly Luo, Kipsigis or Ogiek), land tenure (adjudicated – former native reserve, resettlement scheme, large-scale leasehold, undivided leasehold), water management (non-irrigated, irrigated private land, irrigated government land), land use (type of dominant cash crop, large-scale irrigation), and altitude (floodplain, mid-altitude, higher altitude). For each zone, a rural village was selected that had between 50-100 households.

Through this process, Kiptegan village was selected as a Kalenjin-speaking village located at high altitude, with adjudicated land tenure and rainfed agriculture. In the first months of 2004, a week-long survey was undertaken in Kiptegan by a six-person survey team conducting in-depth interviews with a village representative group, village mapping and household surveys. Group interviews and household surveys revealed a surprisingly high level of social organization around water supplies, with three springs protected and piped, and plans for investment by other groups (Leah Onyango, unpublished data 2005). Kiptegan was therefore identified for a follow-up study of local

social organization, water impacts, and gender relations. The first phase of that study included comparison with a Safeguard village with virtually no collective action for water management. Preliminary results of that comparative study, mostly from key informant and focus group interviews conducted between June and August 2004, are presented in Roy et al. (2005). This paper focuses on more in-depth studies conducted in Kiptegan village in March and April of 2005. The senior author of this paper led the implementation of those in-depth studies.

Kiptegan village offers an interesting range of water management situations, with two groups successfully operating piped water systems, another group in the investment stage of their piped water system, and other groups still relying on unprotected springs. To investigate and clarify factors facilitating and hindering successful community organization, this study identified two groups facing similar opportunities and constraints; one group had succeeded in providing supplies of piped water to their members, one group relied on unprotected springs for their water. Key informant interviews were held with government agricultural, health and water officers at the district and divisional administrative units. At the community level, village elders, chiefs, water committee members, and other community leaders were interviewed. Results from those interviews were cross-checked against earlier interviews conducted in the June – August 2004 period. Topics for discussion included specific roles in improving rural water supply, sources of water, rights to water, opportunities and problems regarding water availability and usage and roles of women and men in water management.

The study also involved six focus group discussions following question guides adapted from the two earlier studies in Kiptegan. Separate group discussions were held with all male members of the Chesilot, Kiptegan and Maimur water projects, with groups of women who currently use, or will use, piped water supplied through those projects and with women currently using unprotected springs and streams. One focus group discussion was mixed, made up of male

and female members of Kiptegan village, of whom some presently use piped water while the rest use unprotected springs. To better understand the role women played in improving water supply, semi structured interviews were held with individual male association and committee members of the piped water projects. To establish impact of improved water on water based activities and social and economic welfare at the household level, individual interviews were held with 30 adult women using protected and piped water and another 39 adult women using unprotected springs and streams. Field assistants accompanied respondents to and from open springs to countercheck respondents' estimates of the amount of time allocated for water collection.

Water sources and water rights

In Ketitui sub location, springs are the main sources of water, with some households located far from springs relying on small streams originating from the springs. Streams are important for all households during dry periods, especially for watering livestock. Rooftop catchments and wells are alternative sources of water. Fifty-three percent of the households who reported using open springs also collected rain water into drums and small pots during the rainy season. Ten respondents indicated that they used water harvested from neighbors' roof tops since they themselves had grass thatched houses inappropriate for collecting rainwater. Wells provide an alternative source of water to a small number of community members who are unable to join gravity water-supply schemes because of being located above the spring heads. Well water is considered unsuitable for drinking and instead is used for watering cattle, cooking and irrigation.

Kiptegan village includes several significant springs, including Kiptegan, Tenduet, Cheribo, Mairmur, Chesilot and Asurur springs. Kiptegan and Chesilot springs

have been protected and piped to members' homesteads, while Mairmur spring is in the process of being protected and piped. Non-members of these groups collect water at the springs and carry it to their homesteads for drinking, watering livestock, and irrigating nurseries for tea seedlings. Women and older children bear almost all of the responsibility for fetching water. Bathing and washing of clothes is mostly done at the springs.

Table 1 lists the various water sources used by people in the Kiptegan area, the location of those water sources, and the way that people obtain access rights to those sources. Springs are located on both individual and public land. In practice, there is very little difference in access between unprotected springs on private land and unprotected springs on public land. Kipsigis social norms hold that land owners must allow access to natural free-flowing water sources, including springs and streams. Previous research conducted in the Nyando basin shows that farmers invariably provide access to unprotected springs via trails across their land, while many farmers cultivate or fence off the trails that provide access to rivers.

Table 1--Rights to sources of water

Source	Location	Rights
Open springs	Individual land	Agreement between land owner and community
	Public land	Open access/longstanding custom
Protected, not piped spring	Public land	General public access
Protected and piped spring	Individual land	Agreement between land owner and user group
Stream and Rivers	Public land	Open access
Wells	Individual land	Maintenance fee by users
Rain water		Agreement between house owner and neighboring households

Source: Key informant and group interviews conducted by the authors, March – April 2005.

Variations from that norm occur for the case of wells and springs in which individual land owners or groups of water users make specific investments in the water point. Prior to the Water Law of 2002, group rights to protected springs could be formally registered with the District Office of the Ministry of Water, with land owners recognizing that right by signing “no objection” forms. Wells are generally considered to be private property and consent is obtained from the land owner before water can be drawn. While there are no fees incurred for drawing water from neighbors’ wells, an annual maintenance fee is charged for cleaning the well and replacing the drawing container.

In the case of springs that are protected and piped to households downhill from the spring, access rights are negotiated with the land owners and other local users of the springs, often through very protracted discussions. Parties involved in the negotiation, acquisition and use of Kiptegan, Chesilot and Maimur water projects include the owner of the land where the springs stand, group members, and the surrounding community (see Box 1).

Once protected (excavated and covered) and piped, management and exclusion rights are held by members of community water associations. During dry seasons water is rationed and irrigation is limited to kitchen gardens for members. Non-members who draw water at Chesilot spring during the wet season are forced to use alternative sources of water as overflow channels run dry during the dry season. Based on the group’s bylaws, non-members can only obtain water from a member’s homestead when one is sick or has visitors. Lack of access to spring water during the dry season has caused animosity between association members and the surrounding community.

Box 1– Negotiations between water groups and landowners**Maimur water project**

Ten initial group members approached the landowner to use the spring and pipe water to their homesteads by gravity feed. The landowner agreed on condition that she would also benefit from the water supplied by the project, but has not yet signed a formal agreement. The landowner is recognized as a committee member and committee meetings are held at her home which makes it easier for her to attend. The landowner indicated that she is happy to participate in the committee in the capacity of a member and leave the higher offices to the men. Being on the committee will allow her easy access to decisions about water access and allocation when water supplies become scarce.

Kiptegan water project

The initial members of the Kiptegan water project were denied access to the first spring that they identified for protection and piping to their downstream homes. The first spring had been protected during the colonial era and continues to provide water for a large number of neighboring households. The group members settled for a second unused spring below the first. They consulted the landowner of the second spring, who already was a member of Chesilot water project and had water piped to his home. He was happy with the initiation of the Kiptegan water project as three of his sons would be members and would benefit from the project. The initial agreement was verbal but he later signed the “no objection” form from the Ministry of Water.

Chesilot water project

Plans to pump water from Asurur stream for cattle and irrigation purposes only were abandoned after three members witnessed a gravity flow scheme at a nearby village. The members thus identified a spring, whose source -coincidentally- was Asurur stream. Unlike the stream, spring water was considered safe to drink and required no further treatment. Thereafter, about 15 members approached the landowner of the Chesilot spring who agreed to its use on the condition that the group constructs two outlets, one for her and one for the community, and a watering point for her cattle. The landowner signed the ‘no objection form’ provided by the Ministry of Water. The assistant chief also signed the form.

Activities around water sources

The 39 female survey respondents who relied on unprotected sources of water were asked questions about activities that are performed, either by themselves or others, around the water points that they use. These questions were designed to uncover explicit or implicit forms of water point management. Potential agents of water pollution as well as conservation measures have been identified.

Apart from being a primary source of water for animals and human beings, springs offer reliable locations for women to hold informal meetings, water livestock and wash clothes. Men, women and children who lack piped water in their homestead often bathe at the springs. For women and older children, trees and shrubs around springs provide an opportunity to collect firewood whereas for men they provide an opportunity to collect timber for sale and charcoal making. In addition, land that abuts a spring is highly valued for agricultural activities due to its proximity to water for bucket irrigation.

Minimal conservation is undertaken in areas surrounding the 'spring head' of both protected and open springs. Excavating the spring head, harvesting and laying of stones as filters are some of the activities carried out mainly by men during spring protection. Cleaning of the water point is undertaken monthly at the Tenduet and Asurur unprotected springs. Among the users of Asurur and Tenduet springs, cleaning is organized by the village elder and involves women and men. People who do not participate are barred from watering their cattle at those particular springs. At the Kiptegan spring, cleaning is undertaken by only women, at their own volition and only at the point for drawing domestic water.

Efforts to plant trees by water users are hindered by lack of control over the use of the land around the spring. At Chesilot spring, cattle owned by the landowner destroyed trees planted by the group. The landowner, who had rejected the group request to fence the area around the spring, has dug trenches and cultivated the area above the spring. Respondents interviewed argued that it was the landowner's responsibility to plant trees and cut them at his/her own discretion.

Lack of standards and enforcing institutions around open springs implies increased degradation of the source as users are free to do as they please. At the Kiptegan, Tenduet and Asurur springs, water is drawn using dirty containers. Poor hygiene standards around the springs reduce the amount of usable water available downstream and increase the waiting time for other users who have to wait for sediment to settle before drawing water.

Table 2--Activities reported to occur around unprotected springs

	Frequency N=39	Percent respondents reporting use
Washing clothes/bathing	27	69.2
Watering cows	27	69.2
Stone harvesting	14	35.9
Cutting of trees	12	30.8
Excavation	12	30.8
Farming	11	28.2
Collection of firewood	9	23.1
Planting of trees	4	10.3
Cleaning the spring	3	7.7
Meeting	2	5.1
Defecating	1	2.6
Charcoal burning	1	2.6

IMPACTS OF IMPROVED WATER SUPPLIES

This section of the paper reports on the impacts of improved water supplies on water consumption, water allocation, and associated changes in livelihoods. Impacts of improved water supplies were calculated two ways: by comparing households currently with and without improved water supplies and by comparing before and after situations for households currently with improved water supplies.

Water allocation: time and uses

The 39 sample households that used an unprotected communal spring as their primary source of water reported using an average of 16.6 hours per week during the dry season and 6.5 hours per week during the rainy season to collect and carry water back and forth from the spring (see Table 3). The amount of time used during the dry season is almost triple that used in the wet season. As indicated earlier, 53 percent of users harvest rainwater during the wet season, reducing the number of times they need to travel to the spring. Each trip to collect water during the dry season may also take longer, as there is a high concentration of users at the spring and less water running from the spring. Table 4 illustrates the amount of time taken to fill a 20 liter Jeri can at various sources during the wet and dry season. Besides a decrease in water volume during the dry season, the manner in which the container is filled influences the total time allocated for water collection. For example, at Chesilot during the wet season users take five seconds to fetch water from the existing overflow pipe / outlet; at Tenduet spring people use a smaller container to fill their Jeri cans, requiring up to two minutes to do so.

Table 3--Amount of time spent collecting water in the dry and wet seasons (n = 39)

Season	Minimum reported hours per week	Maximum reported hours per week	Average hours per week
Dry season	1.05	70	16.6
Wet season	0.47	28	6.5

Tenduet Spring	3 minutes	2 minutes
Tenduet stream	3 minutes	2 minutes
Asurur spring	5 minutes	25 sec
Chesilot spring	not available	5 sec

Source: Survey of 39 women who rely on water from unprotected springs

Because of the high variation in the amount of time that households report taking to collect water, field assistants were tasked to stay by the springs, then walk home with some of the women who came to collect water. The results suggested some clear over-estimates by the respondents. One woman indicated that it would take 30 minutes to walk home, when in fact it took only five minutes. Another woman indicated that it would take 60 minutes to walk home, when in fact it took 20 minutes. Several factors may explain this discrepancy. On one hand, the women do not wear watches and may not have a clear sense of time. On the other hand, drawing water from the spring provides one of the only chances that most women have for meeting friends, washing clothes and bathing. The extra time may also be tacitly used to monitor and sanction use of the spring. Overall these results call for a detailed longitudinal study and the use of more appropriate techniques for measuring time allocation.

On average during the dry season, households with piped water reported spending 69 minutes per day collecting water, 33 minutes less than the amount before improved supply and 73 minutes less than the amount used by non members in search of water. The 30 respondents with improved water supply reported that they used the time savings to work in the farm (28 respondents), attend women's meetings (seven respondents), trade in the market (seven respondents), clean themselves and the compound (two respondents), water cattle (two respondents), prepare meals (one respondent) and collect firewood (one respondent).

Increased water use

Table 5 provides results on the total amounts of water reported to be used by 30 households before and after they had piped water available in their compounds, and

compares those amounts to the amounts reported by the 39 sample households that did not have access to piped water. The average amount reported for households without piped water (100.5 liters per day) is fairly similar to the average amount reported for piped water households before they obtained the piped water sources (84.5 liters per day). Households with piped water reported using 2.8 times more water after piped water was available than they did before they had piped water and 2.4 times more water than households without piped water.

Table 5--Daily water use before and after improved supply due to piped water

	N	Minimum number of liters per day	Maximum number of liters per day	Mean number of liters per day
Current users of piped water after improved supply	30	40.0	600.0	236.2
Current users of piped water before improved supply	30	0	200.0	84.5
Current users of unprotected communal springs	39	5.0	280.0	100.5

Source: Calculations based on household surveys of 30 women using water from protected and piped sources and 39 women using water from unprotected springs

Table 6 provides data on the major uses of water for the 30 households with piped water and the 39 households without piped water. Note that the sum of these individual uses of water is much higher than the total water collection in those households reported in Table 6, with the aggregate over-estimate almost 100 liters per day for households with piped water and 80 liters per day for households without piped water. We consider the estimates of total water use from Table 6 to be much more reliable than the quantitative estimates of water allocation to the different uses. We therefore focus on the percentages of water reported for the different uses (columns 3 and 5) than on the amounts of water reported for each individual use.

Table 6--Average daily water consumption for households with and without piped water

Household use of water	Average liters used per day reported by households with piped water	% of water by use reported by households with piped water	Average liters used per day in households without piped water	% of water by use reported by households without piped water	Average higher consumption in households with piped water	% higher consumption in households with piped water
Livestock consumption	94.0	28.1	64.4	35.5	29.6	46
Kitchen garden irrigation	45.7	13.7	15.7	8.7	29.9	190

Total	334.2		181.4		152.8	84

Source: Calculations based on household surveys of 30 women using water from protected and piped sources and 39 women using water from unprotected springs

The five major uses of water in houses with piped water are livestock, kitchen gardens, bathing, washing clothes and tea seedlings. In households without piped water, livestock again was the highest water consumer followed by watering tea seedlings, cooking, washing utensils, and watering kitchen gardens. Households with piped water use a much higher proportion of their water for washing clothes and a much lower proportion for human consumption. The largest proportionate increases in water use for

households with piped water were washing clothes, watering kitchen gardens, and bathing.

The total amount of water allocated for productive uses is higher than the amount utilized for domestic purposes for both households with piped water and households without piped water. Households with piped water reported using 52.9 percent of their daily water use for watering livestock, watering kitchen garden and watering tea seedlings (productive purposes), and 47.1 percent of their daily water use for drinking, cooking, washing clothes and bathing (reproductive purposes). Households without piped water reported using 56.5 percent of their daily water use for productive purposes and 43.5 percent for reproductive purposes.

The indicated total amount of water used by households without piped water is not exhaustive as activities such as bathing; washing of clothes and watering of the cattle are undertaken at the stream, making it difficult to quantify the amount of water used.

Health benefits of improved water supply

Households with piped water were also asked to provide their perceptions of the benefits of the improved water supply. Of 30 households with improved water supply, reduced incidences of waterborne diseases were reported by 25 respondents, and frequent clothes washing and bathing were reported in 24 and 23 households, respectively. Other health benefits included reduction in skin infection and washing of utensil after every meal (previously utensils were washed once a day, after lunch) (see Table 7).

Table 7--Health benefits associated with piped water supplies

Advantage associated with piped water among households gaining piped water (n = 30)	Number of households noting this advantage (n =30)
Less water borne diseases	25
Clothes washed more	24
Bathing more	23
Smear floors each week	6
Less rush	4
Utensils washed more	3
No need to boil water	2
No discolored clothes	2
Less fatigue	1

Impacts of improved water supply on agricultural production and sale

The 30 households with improved water supply were also asked a series of questions about the impacts on agriculture. The results are displayed in Figure 1. Increased supply of indigenous vegetables was reported by 24 households, increased milk production was reported by 20 households, increased production of tea seedlings was reported by 15 households, and increased production of tomatoes was reported by eight households. The 15 households reporting increased production of tea seedlings produced between 100 and 7000 tea seedlings. These products were important sources of monetary income for the households with improved water supply: 76 percent of them sold milk, 76 percent sold indigenous vegetables, 66 percent sold tea leaves, and 30 percent sold tomatoes.

Other impacts noted by a few households were less livestock disease – due to more frequent spraying of livestock at the homestead and less interaction with other cattle, increase in the number of livestock, introduction of improved cattle breeds,

increase in eggs laid, planting of napier grass and cultivation of fruits. Also, two households indicated planting and harvesting maize twice a year compared to only once before improved water supply. Livestock, fruit and chickens were sold by small numbers of households.

Figure 1—Effects on agriculture of improved water supply, reported by households with piped water

Source: Survey of 30 women with improved water supplies. (No. of households indicates the number of women respondents with piped water who reported each item as a beneficial effect of the improved water supply)

Households with improved water supply were also asked questions about who controlled different sources of household income (Table 8). Joint control of income by husbands and wives is relatively uncommon. Husbands tend to control income from the sale of tea leaves and tomatoes, while wives tend to control income from indigenous vegetables. Milk is a special case. In most households, women are in charge of evening

milk sales and men in charge of morning sales. Evening produce is often sold in bottles to neighboring homesteads while morning milk tends to be sold at the outlet of the cooperative society. It was noted that women would continue to control evening sales provided that the milk produced was limited to a few bottles. A larger increase in the quantity of evening milk would require delivery of milk to cooperative societies. This would lead to the involvement of men, who are the registered members of the cooperative societies, rather than their wives.

Table 8--Control of income from various activities

Source: Survey of 30 women with improved water supplies

Other benefits of improved water supply

Other benefits noted during the group interviews include: time for relaxation, visiting friends and relatives, men spending more time doing casual work as they no longer have to hurry home to bathe at the river before dusk, and increased cohesion between wives and husbands as cattle are watered and meals are prepared on time. Children, notably girls, are arriving promptly at school as they are no longer required to

fetch water before and after school. Except in a few cases where men reported working long hours doing casual labor, for most men improvement in water supply did not result in an increase of activities. In contrast, activities undertaken by women increased considerably. This may be a result of women being 'freed' from fetching water and thus able to utilize the time saved doing extra activities.

A significant outcome of the water projects has been the formation of Chesilot and Kiptegan women's groups which raised funds for implementation of the water projects on one hand and purchased household goods and /or paid school fees on the other.

Noted from the survey was the increased collaboration between members and wives of Chesilot and Kiptegan water project. The men with the help of local chief and local authority spearheaded the construction of Kiptegan primary school which has benefited the entire community. In the past, the nearest primary school was in Kapsoit, 10 kilometers away.

SOCIAL ORGANIZATION FOR IMPROVING WATER SUPPLIES

In this section we examine factors facilitating implementation and successful operation of water associations in the study area. The following three paragraphs provide short descriptions of how the Maimur, Chesilot, and Kiptegan water projects were established.

The Chesilot water project was the first water association in the administrative sub-location. It was initiated by a farming group, consisting of 10 men in a self-help group focused on tea and dairy farming. In the face of severe drought and resultant poor

yields, the group considered investing in a hydram, or hydraulic pump, that would use the force of gravity to pump water uphill from their normal water point, but abandoned the idea after three of its members on a field visit to Sociot, a nearby village, observed people drinking water at their homes without the use of a pump, simply by gravity. They decided to replicate what they had observed. Back at home, the three members – the village elder, the current treasurer (village elder's son) and the current secretary -- informed other members about the new technology. The group recruited 30 more members, all of whom live downstream from their source spring. All members are from Chesilot village. As we report below, women's roles in the initiation of the Chesilot project have largely been hidden in the narrative told by the committee members. By all accounts, the Chesilot water project continues to be a strong social institution that enhanced social cohesion among men and women and improved livelihoods for its members.

The Kiptegan water project was initiated soon after the Chesilot project succeeded in installing water stand pipes in the homesteads of all 40 members. Members of the Kiptegan group decided to replicate the success of Chesilot and another nearby water project, Kipkabur. The Kiptegan group has 17 male members who receive water at household taps and provide piped water to a church. Providing water to dairy cattle appears to be the main impetus for the project. The research revealed that the Kiptegan water project is not a strong social institution. The water project has strained social relations and there is mistrust among members and between men and women.

The Maimur water project was at the initial stage of spring protection at the time of this study —excavation and laying of stones to construct the water reservoir. The group is made up of 40 households from Ketitui village. Unlike Chesilot and Kiptegan

water projects, all the members live upstream and will use a hydram to pipe water into their homestead. The women of Maimur have consistently lobbied for improving water supply. The impetus for initiation of the water project emanated from women who have progressively advocated for improvement of water supply, first by mobilizing the users to separate watering points for livestock and humans, and thereafter by urging their husbands to protect the spring head and pump water into their homesteads. Women often have informal meetings at the spring where they discuss ways of improving water supply.

Registration of the community water projects

Once a suitable spring was identified, group members approached the landowner who is the de facto owner of the spring as it is situated on his/her land. He/she then stipulated conditions (see box 2) to be fulfilled before he/she approved allocation of the spring for protection and piping.

For Kiptegan and Chesilot water projects, once a verbal agreement was reached, the landowner was presented with a 'no objection form' to sign from the Ministry of Water. It was then given to the assistant chief for confirmation and approval. Subsequently, the groups registered with the Ministry of Social Services but only after electing officials and writing project constitution/bylaws. Maimur water project is yet to be formalized and is currently operating on a verbal agreement.

Conflicts affecting the community water projects

With diminishing water during the dry season, a result of persistent droughts and poor land uses, conflicts (though not violent) range from vandalism to quarrels between women waiting to fetch water, to increased tension between landowner and user groups

as well as non members and user groups. There have been repeated cases of vandalism of the Chesilot, presumably due to jealousy among nearby households that downstream households are deriving benefits from the spring, with little benefit to those who live closest to the spring. There is also some tension between the Chesilot group and the owners of the land on which the spring is located. When the group approached the spring 'owner', a verbal agreement between the man and the group was reached on the need to protect the spring, plant trees and fence the catchment area. When he passed away, his wife did not honor the agreement and began cultivating and digging trenches above the spring. The group's effort at protecting the catchment area was thwarted when her cattle destroyed young trees planted. Attempts to resolve the conflict hit a snag when the landowner failed to attend a meeting convened by the chief. The chief indicated he could only negotiate between the two parties but had no mandate to censure the landowner for her actions.

At Kiptegan spring, members of Kiptegan water project were obstructed from protecting the source by the owner of the land and the surrounding community, both claiming long standing traditional rights to the spring. Current users claim the group commenced protecting the spring without consulting existing users and landowner. This claim was corroborated by a member of the project.

The most cost efficient approach to improving water supply is by gravity scheme; this is however limited to those living downstream from the location of the spring, excluding upstream users. To this end, upstream users often object to the protection of springs and piping of water. For community members unable to join a water association, spring protection poses a threat to water security. Protection of the Chesilot spring

reduced the amount of water available to the surrounding community during the dry season. As a result, tension is high and several cases of vandalism have been reported.

Participation by women and men

Operations and daily deliberations of activities in the water projects are coordinated by committee and group members. Group meetings of the committee are held once per week in Chesilot water project, once per month in Kiptegan water project and twice per week in Maimur water project. Committee meetings are held either late in the afternoon (Maimur water project) or in the evening (Chesilot water project) making it very difficult for women, who are responsible for preparing evening meals and childcare, to participate. With the exception of the female landowner in Maimur Water project, committee and association membership in the existing water associations is exclusive to men. The only registered female member of Chesilot water project recently relinquished her position to her son. As described in the following section, some women do attend the semi-annual general meetings of the projects and participate actively in women's groups associated with the projects.

From the group discussions in Chesilot and Kiptegan, men do appear to have taken lead roles in initiation and implementation phases of the project. However, in a key informant interview, the Chesilot village elder did acknowledge the role played by women in the initiation of the project and noted their wise decision to raise money through the sale of tea seedlings. Another male member admitted joining the group due to his wife's initiative. His wife sold two chickens for about Ksh.500 to pay the initial registration fee. Individual interviews with group members and wives of group members further revealed the active participation of women. During project implementation, men

harvested stones, excavated the spring head and protected it, and dug trenches and laid pipes. Figure 2 illustrates that women prepared meals, an activity primarily considered to be a woman's task, but they also went a step further and paid registration fees, ferried stones to the implementation site, and undertook duties (digging trenches, constructing the source and tank) assigned to their husbands when the latter were absent.

At Maimur water project, separate group discussions held with women and men plainly identified women who met informally at the spring as project initiators. In discussions held with non members, initiation of projects is seen as the responsibility of women, as they bear the brunt of fetching water from distant sources and undertake most if not all domestic and farm work. Once they have identified an appropriate technology and passed on information to their spouses, it is the men's responsibility to implement the project. Women are expected to raise a smaller proportion of funds for the project as compared to men.

As seen in Table 9, there is a shift in activities undertaken by women once water has reached the homestead. Worth noting is the increase in the number of women attending annual general meetings from four during the construction phase of projects to 16 after completion of construction. They continue to prepare meals when meetings are held in their homes. A few women however, were not involved in any activities.

Table 9--Water management activities undertaken by women before and after construction of protected and piped water systems (n = 30)

Activity	Before completion of construction	After completion of construction
Preparing meals	16	6
Source construction	6	0
Tank construction	0	13
Not involved	4	6
Attending semi-annual general meetings	4	16
Purchase of sand	1	1
Carrying stones	4	2
Digging trenches	7	0
Registration fee	6	0
Pipes	2	0
Urging defaulters to pay	0	1
Maintenance fee/fine	0	5

Source: Household survey of 30 women involved in the Chesilot and Kiptegan water projects

Womens' groups and water management

As earlier indicated, women are not recognized as members of water projects and committees, although some wives of the many male members do participate in general meetings of the membership. Women have instead opted to form separate groups, with their own committees. The Kiptegan women's group was initiated after women felt marginalized in the water project. In the words of Leah Mosoin, a villager drawing water from communal springs:

'After members meet and agree on those to be given official positions women are mostly left out. The only option for women is to form their own group within the project and elect their own officials. For the group (women) they intend to finance part of the

project costs. The women can contribute an amount decided by them in order to aid in the financing of the project’.

The Chesilot women’s group (previously called *anyiny bei* (sweet waters)) was formed when wives of members of the Chesilot water project organized a festival to express their appreciation of their husband’s role in improving water supply. To raise funds they engaged in informal labor groups, harvesting and weeding farms for payment. Money obtained was invested in planting of tea seedlings which were later sold for a total amount of ksh. 25,000. Part of the proceeds was distributed amongst members and the balance used to purchase maize to be put aside and sold at a higher price during the dry season. Each member also contributed Ksh. 500 for repaying loans which had been obtained by men for constructing the reservoir tank.

In addition to informal harvesting groups, women’s groups have revolving funds where part of the money is contributed to the water project. The Kiptegan women’s group has a revolving fund made up of 16 members, each of whom contributing Ksh.100 towards the kitty. From monthly collection of Ksh 1600, the women donated Ksh.500 towards the spring protection and purchase of pipes. The balance was given to the host to be used to purchase household items.

Factors influencing effective collective action

Members of Kiptegan and Chesilot water projects have collectively initiated and managed water projects and are currently enjoying improved economic, physical and social wellbeing. A section of the community has been unable both individually and collectively to improve water supply. They in turn face numerous challenges ranging from contaminated water, long distances to fetch water, steep slopes, and long queues to

uncertain access to water resources. The success of the water projects can be credited to several factors including:

- Members understood the value of pooling efforts and resources to solve a shared problem. The initial 10 members of Chesilot water project recruited more members to raise funds for the construction and protection of the spring head. During the second phase of the project, ‘laying pipes to individual homesteads’, members agreed to collectively contribute money to purchase pipes in view of the fact that the number of pipes required to reach one’s homestead depended on the distance of the homestead from the ‘source.’

‘If we constructed the main pipe and asked everyone to get own pipes, some would not have afforded, so we decided that all members should work for all. Other members required only five pipes (20 ft each) while others needed 30 pipes’ (interview with Mr. Kiget, chairman of Chesilot water project. March, 11 2005.)

- Membership was limited to individuals from the same village. At Chesilot, members belonged to one clan. At Kiptegan all of the members belonged to the village church, which also received water from the distribution pipe belonging to the group. This provided enhanced cohesion among members. Special emphasis was placed on the conduct of members during and after meetings. High discipline among members meant high attendance at weekly meetings, payment of dues on time and conflicts deliberated upon and resolved at meetings.
- Awareness and enforcement of written and unwritten bylaws. All of the members interviewed and some of their wives were aware of the group’s bylaws. Sanctions are also in place to deal with defaulters. At Chesilot water project, rules and sanctions were observed and applied meticulously. For example, failure to pay maintenance resulted in the amount being doubled and water being disconnected until payment was finalized. Water is also disconnected when one fails to report tap breakage immediately after it occurs. Moreover, one member was kicked out

- of the group when he failed to participate in group activities for two consecutive days without offering an explanation for his absence or paying a fine of Ksh. 200.
- Chesilot and Kiptegan groups are composed of educated members and officials with good writing and record keeping skills. The chairman of Chesilot group and one member of Kiptegan group are health officials at the district hospital and a local non governmental agency, respectively. Also at Chesilot, the secretary, treasurer and village elder are widely traveled with the latter having been a soldier during the Second World War. Thus, they appreciate the role of water in promoting good health and agricultural and economic activities.
 - A combination of good governance and transparency is enshrined in the management of the project. Records are easily available for inspection by members during the weekly meetings and by members and their wives during the annual general meeting held once every six months. Moreover, officials were elected based on their generosity, determination and on their geographic location within the village. The latter would enable them to monitor how members use water.

“...we have a general meeting twice a year. At these meetings, we give the financial records to the whole group. People are reminded of the payments they owe. And they are shown how the money was spent and how much money is remaining. We have a bank account. At least two people have to withdraw money from the account.” Reuben Tanui, treasurer of Chesilot water project, August 2004. (Source: Field notes of the late Jessica Roy)

- The division of labor is characterized by reciprocity and complementarity of gender roles. Men raise a larger proportion of project funds, women raise a smaller proportion; women report vandalism, men take care of vandalism; women guard against breakages in the home, men do the plumbing work. Men appreciate the importance of time spent by women in search of water and acknowledge that the time saved by improving the water supply can be used productively. Consequently, at Chesilot and Kiptegan groups, men initiated water projects

which benefited the entire household, particularly the women. At Maimur, women initiated the project but left it up to the men to organize its implementation.

Women, for their part, prepared meals for the men during construction. They also formed women's groups, in which they raised funds by planting and selling tea seedlings, engaging in casual labor and revolving funds. Women organized themselves into *morik* (informal harvesting groups) to raise funds. They also capitalized on the premise that through their initiative, by working together as women, it becomes easy for their spouses and the entire community to do the same.

- Membership is small and closed to new members. Members argue that the fewer they are, the more water there will be available in each household. It is also easier for the officials to monitor and coordinate activities when the group is small.
- Tangible benefits to individual members from collective efforts of supply and distribution of water acted as incentives to continued cooperation. The ability to plant tomatoes, tea seedlings and indigenous vegetables during the dry season calls for continued supply of water. Individual households thus strive to pay maintenance fees, as failure to do so may result in disconnection of water.

CONCLUSIONS

The case studies presented in this paper illustrate how rural communities successfully mobilized local investment in water systems in an environment where most groups have failed to do so. Safe and easily accessible water has brought a range of benefits to those households, especially through activities where women have special responsibilities. Households with improved water access report time savings, improved health, cleaner clothes, and increased production of tea seedlings, milk and vegetables, with the net result of significant increases in income controlled by women. These case studies thus provide solid support for the proposition that access to small amounts of water beyond domestic needs can lead to substantial improvements in welfare, especially for women (Moriarty, Butterworth, and van Koppen 2003).

Collective action is seen to achieve greater impact when the division of labor is characterized by reciprocity, when men and women negotiate their rights deliberately and undertake activities complementing each other and when trust and social cohesion is strong between men and women. In contrast, discussions with users of communal springs suggest collective action will fail when trust relations are breached, especially when funds are misappropriated, when there is a lack of information flow between the men who attend meetings and their wives who are the chief direct users of the water, and when there is a lack of trust between women and men. Men must trust that women will use their enhanced time and water resources for the good of all household members.

Despite the obvious obstacles, a significant number of community groups in this part of Kenya have mobilized themselves to protect and pipe water to their members' homesteads. Policy makers and planners must see community groups as important water

service suppliers and adjust policies and programs accordingly. Kenya's current Water Policy appears to be more biased toward the regulation of larger-scale private and non-governmental suppliers of water, rather than toward the facilitation of small community groups. Community groups would benefit greatly from reliable technical input into water system design, institutional support for group formation and conflict resolution, and cost sharing of infrastructure investments.

List of CAPRI Working Papers

- 01 Property Rights, Collective Action and Technologies for Natural Resource Management: A Conceptual Framework, by Anna Knox, Ruth Meinzen-Dick, and Peter Hazell, October 1998.
- 02 Assessing the Relationships between Property Rights and Technology Adoption in Smallholder Agriculture: A Review of Issues and Empirical Methods, by Frank Place and Brent Swallow, April 2000.
- 03 Impact of Land Tenure and Socioeconomic Factors on Mountain Terrace Maintenance in Yemen, by A. Aw-Hassan, M. Alsanabani and A. Bamatraf, July 2000.
- 04 Land Tenurial Systems and the Adoption of a Mucuna Planted Fallow in the Derived Savannas of West Africa, by Victor M. Manyong and Victorin A. Houndékon, July 2000.
- 05 Collective Action in Space: Assessing How Collective Action Varies Across an African Landscape, by Brent M. Swallow, Justine Wangila, Woudyalew Mulatu, Onyango Okello, and Nancy McCarthy, July 2000.
- 06 Land Tenure and the Adoption of Agricultural Technology in Haiti, by Glenn R. Smucker, T. Anderson White, and Michael Bannister, October 2000.
- 07 Collective Action in Ant Control, by Helle Munk Ravnborg, Ana Milena de la Cruz, María Del Pilar Guerrero, and Olaf Westermann, October 2000.
- 08 CAPRI Technical Workshop on Watershed Management Institutions: A Summary Paper, by Anna Knox and Subodh Gupta, October 2000.
- 09 The Role of Tenure in the Management of Trees at the Community Level: Theoretical and Empirical Analyses from Uganda and Malawi, by Frank Place and Keijiro Otsuka November 2000.
- 10 Collective Action and the Intensification of Cattle-Feeding Techniques a Village Case Study in Kenya's Coast Province, by Kimberly Swallow, November 2000.
- 11 Collective Action, Property Rights, and Devolution of Natural Resource Management: Exchange of Knowledge and Implications for Policy, by Anna Knox and Ruth Meinzen-Dick, January 2001.

- 12 Land Dispute Resolution in Mozambique: Evidence and Institutions of Agroforestry Technology Adoption, by John Unruh, January 2001.
- 13 Between Market Failure, Policy Failure, and “Community Failure”: Property Rights, Crop-Livestock Conflicts and the Adoption of Sustainable Land Use Practices in the Dry Area of Sri Lanka, by Regina Birner and Hasantha Gunaweera, March 2001.
- 14 Land Inheritance and Schooling in Matrilineal Societies: Evidence from Sumatra, by Agnes Quisumbing and Keijuro Otsuka, May 2001.
- 15 Tribes, State, and Technology Adoption in Arid Land Management, Syria, by Rae, J, Arab, G., Nordblom, T., Jani, K., and Gintzburger, G., June 2001.
- 16 The Effects of Scales, Flows, and Filters on Property Rights and Collective Action in Watershed Management, by Brent M. Swallow, Dennis P. Garrity, and Meine van Noordwijk, July 2001.
- 17 Evaluating Watershed Management Projects, by John Kerr and Kimberly Chung, August 2001.
- 18 Rethinking Rehabilitation: Socio-Ecology of Tanks and Water Harvesting in Rajasthan, North-West India, by Tushaar Shah and K.V.Raju, September 2001.
- 19 User Participation in Watershed Management and Research, by Nancy Johnson, Helle Munk Ravnborg, Olaf Westermann, and Kirsten Probst, September 2001.
- 20 Collective Action for Water Harvesting Irrigation in the Lerman-Chapala Basin, Mexico, by Christopher A. Scott and Paul Silva-Ochoa, October 2001.
- 21 Land Redistribution, Tenure Insecurity, and Intensity of Production: A Study of Farm Households in Southern Ethiopia, by Stein Holden and Hailu Yohannes, October 2001.
- 22 Legal Pluralism and Dynamic Property Rights, by Ruth Meinzen-Dick and Rajendra Pradhan, January 2002.
- 23 International Conference on Policy and Institutional Options for the Management of Rangelands in Dry Areas, by Tidiane Ngaido, Nancy McCarthy, and Monica Di Gregorio, January 2002.
- 24 Climatic Variability and Cooperation in Rangeland Management: A Case Study From Niger, by Nancy McCarthy and Jean-Paul Vanderlinden, September 2002.

- 25 Assessing the Factors Underlying the Differences in Group Performance: Methodological Issues and Empirical Findings from the Highlands of Central Kenya, by Frank Place, Gatarwa Kariuki, Justine Wangila, Patti Kristjanson, Adolf Makauki, and Jessica Ndubi, November 2002.
- 26 The Importance of Social Capital in Colombian Rural Agro-Enterprises, by Nancy Johnson, Ruth Suarez, and Mark Lundy, November 2002.
- 27 Cooperation, Collective Action and Natural Resources Management in Burkina Faso: A Methodological Note, by Nancy McCarthy, Céline Dutilly-Diané, and Boureima Drabo, December 2002.
- 28 Understanding, Measuring and Utilizing Social Capital: Clarifying Concepts and Presenting a Field Application from India, by Anirudh Krishna, January 2003.
- 29 In Pursuit Of Comparable Concepts and Data, about Collective Action, by Amy Poteete And Elinor Ostrom, March 2003.
- 30 Methods of Consensus Building for Community Based Fisheries Management in Bangladesh and the Mekong Delta, by Parvin Sultana and Paul Thompson, May 2003.
- 31 Formal and Informal Systems in Support of Farmer Management of Agrobiodiversity: Some Policy Challenges to Consolidate Lessons Learned, by Marie Byström, March 2004.
- 32 What Do People Bring Into the Game: Experiments in the Field About Cooperation in the Commons, by Juan-Camilo Cárdenas and Elinor Ostrom, June 2004.
- 33 Methods for Studying Collective Action in Rural Development, by Ruth Meinzen-Dick, Monica Di Gregorio, and Nancy McCarthy, July 2004.
- 34 The Relationship between Collective Action and Intensification of Livestock Production: The Case of Northeastern Burkina Faso, by Nancy McCarthy, August 2004.
- 35 The Transformation of Property Rights in Kenya's Maasailand: Triggers and Motivations by Esther Mwangi, January 2005.
- 36 Farmers' Rights and Protection of Traditional Agricultural Knowledge, by Stephen B. Brush, January 2005.

- 37 Between Conservationism, Eco-Populism and Developmentalism – Discourses in Biodiversity Policy in Thailand and Indonesia, by Heidi Wittmer and Regina Birner, January 2005.
- 38 Collective Action for the Conservation of On-Farm Genetic Diversity in a Center of Crop Diversity: An Assessment of the Role of Traditional Farmers' Networks, by Lone B. Badstue, Mauricio R. Bellon, Julien Berthaud, Alejandro Ramírez, Dagoberto Flores, Xóchitl Juárez, and Fabiola Ramírez, May 2005.
- 39 Institutional Innovations Towards Gender Equity in Agrobiodiversity Management: Collective Action in Kerala, South India, by Martina Aruna Padmanabhan, June 2005.
- 40 The Voracious Appetites of Public versus Private Property: A View of Intellectual Property and Biodiversity from Legal Pluralism, by Melanie G. Wiber, July 2005.
- 41 Who Knows, Who Cares? Determinants of Enactment, Awareness and Compliance with Community Natural Resource Management Bylaws in Uganda, by Ephraim Nkonya, John Pender, Edward Kato, Samuel Mugarura, and James Muwonge, August 2005.
- 42 Localizing Demand and Supply of Environmental Services: Interactions with Property Rights, Collective Action and the Welfare of the Poor, by Brent Swallow, Ruth Meinzen-Dick, and Meine von Noordwijk, September 2005.
- 43 Initiatives for Rural Development through Collective Action: The Case of Household Participation in Group Activities in the Highlands of Central Kenya, By Gatarwa Kariuki and Frank Place, September 2005.
- 44 Are There Customary Rights to Plants? An Inquiry among the Baganda (Uganda), with Special Attention to Gender, by Patricia L. Howard and Gorette Nabanoga, October 2005.
- 45 On Protecting Farmers' New Varieties: New Approaches to Rights on Collective Innovations in Plant Genetic Resources by Rene Salazar, Niels P. Louwaars, and Bert Visser, January 2006.
- 46 Subdividing the Commons: The Politics of Property Rights Transformation in Kenya's Maasailand, by Esther Mwangi, January 2006.
- 47 Biting the Bullet: How to Secure Access to Drylands Resources for Multiple Users, by Esther Mwangi and Stephan Dohrn, January 2006.

- 48 Property Rights and the Management of Animal Genetic Resources, by Simon Anderson and Roberta Centonze, February 2006.
- 49 From the Conservation of Genetic Diversity to the Promotion of Quality Foodstuff: Can the French Model of ‘Appellation d’Origine Contrôlée’ be Exported? by Valérie Boisvert, April 2006.
- 50 Facilitating Collective Action and Enhancing Local Knowledge: A Herbal Medicine Case Study in Talaandig Communities, Philippines, by Herlina Hartanto and Cecil Valmores, April 2006.
